

Telogen Effluvium

Telogen effluvium is a condition in which more than normal amounts of hair fall out. There is a general 'thinning' of the hair. Unlike some other hair and scalp conditions, it is temporary and the hair growth normally recovers.

The normal life cycle of scalp hair

Hair is made in tiny pouches in the skin called hair follicles. Each scalp hair has a normal 'life cycle'. Most scalp hairs last about 3 years and grow about 1 cm a month. After a period of time (about 3 years), each hair on the scalp comes to the end of its life and falls out. The hair follicle rests for a short while. It then starts to make a new hair.

All the hairs on the scalp are at different stages in their life cycle. At any one time about 1 in 100 scalp hairs are at the end of their life ready to fall out. This is why a few hairs are normally found on shoulders and some fall out each time the hair is washed.

What are the symptoms of telogen effluvium?

People with telogen effluvium notice that a lot of hairs fall out from their scalp. This is more than normal and most noticeable when washing the hair. However, the scalp and the remaining hair look healthy. There are no patches of hair loss (bald patches) but rather a generalized thinning.

Who gets telogen effluvium?

Telogen effluvium usually occurs about 1-3 months after a major stress to the body. The most common time it occurs is in women about 1-3 months after childbirth. Other times include 1-3 months after a major operation, accident or illness.

Why does telogen effluvium occur?

A major stressful event such as childbirth or major surgery can interrupt and stop the growth of some hairs. It tends to affect older hairs, which are brought to an end of their life cycle earlier than the usual 3 years or so. Many more hairs than usual are then ready to fall out. It takes 1-3

months for the affected hairs to fall out after their growth has stopped. After a short time, new hairs then grow from the hair follicles as usual. A normal pattern and thickness of hair returns within a few months once these new hairs are established.

What is the treatment for telogen effluvium?

No treatment is available or required. The hair will naturally return to normal within a few months.
